

## Bell Laboratories

Subject: File-

date: **November 2, 1997**

from:

Normally, the order of items does not matter. The only exception is that if there are multiple authors (%A lines) the order of authors should be that on the paper. If a line is too long, it may be continued on to the next line; any line not beginning with % or . (dot) is assumed to be a continuation of the previous line. Again, see the first article above for an example of a long title. Except for authors, do not repeat any items; if two %J lines are given, for example, the first is ignored. Multiple items on the same file should be separated by blank lines.

Note that in formatted printouts of the file, the exact appearance of the items is determined by a set of macros and the formatting programs. Do not try to adjust fonts, punctuation, etc. by editing the data base; it is wasted effort. In case someone has a real need for a differently-formatted output, a new set of macros can easily be generated to provide alternative appearances of the citations.

### 1. Updating and Re-indexing.

This section describes the commands that are used to manipulate and change the data base. It explains the procedures for (a) finding references in the data base, (b) adding new references, (c) changing existing references, and (d) deleting references. Remember that all changes, additions, and deletions are done by preparing separate files and then running an 'update and reindex' step.

*Checking what's there now.* Often you will want to know what is currently in the data base. There is a special command *lookbib* to look for things and print them out. It searches for articles based on words in the title, or the author's name, or the date. For example, you could find the first paper above with

```
lookbib aho ullman maximal subsequence 1976
```

Letter	Meaning	Letter	Meaning
A	Author	K	Extra keys
B	Book including item	N	Issue number
C	City of publication	O	Other
D	Date	P	Page numbers
E	Editor of book	R	Report number
I	Publisher (issuer)	T	Title of item
J	Journal name	V	Volume number

Note that

*%B*

is used to indicate the title of a book containing the article being entered; when an item is an entire book, the title should be entered with a

*%T*

as usual.

or

```
lookbib aho ullman hirschberg
```

If you don't give enough words, several items will be found; if you spell some wrong, nothing will be found. There are around 4300 papers in the public file; you should always use this command to check when you are not sure whether a certain paper is there or not.

*Additions.* To add new papers, just type in, on one or more files, the citations for the new papers. Remember to check first if the papers are already in the data base. For example, if a paper has a previous memo version, this should be treated as a change to an existing entry, rather than a new entry. If several new papers are being typed on the same file, be sure that there is a blank line between each two papers.

*Changes.* To change an item, it should be extracted onto a file. This is done with the command

```
pub.chg key1 key2 key3 ...
```

where the items key1, key2, key3, etc. are a set of keys that will find the paper, as in the *lookbib* command.

That is, if

```
lookbib johnson yacc cstr
```

will find a item (to, in this case, Computing Science Technical Report No. 32, "YACC: Yet Another Compiler-Compiler," by S. C. Johnson) then

```
pub.chg johnson yacc cstr
```

will permit you to edit the item. The *pub.chg* command extracts the item onto a file named "bibxxx" where "xxx" is a 3-digit number, e.g. "bib234". The command will print the file name it has chosen. If the set of keys finds more than one paper (or no papers) an error message is printed and no file is written. Each reference to be changed must be extracted with a separate *pub.chg* command, and each will be placed on a separate file. You should then edit the "bibxxx" file as desired to change the item, using the UNIX editor. Do not delete or change the first line of the file, however, which begins *%#* and is a special code line to tell the update program which item is being altered. You may delete or change other lines, or add lines, as you wish. The changes are not actually made in the public data base until you run the update command *pub.run* (see below). Thus, if after extracting an item and modifying it, you decide that you'd rather leave things as they were, delete the "bibxxx" file, and your change request will disappear.

*Deletions.* To delete an entry from the data base, type the command

```
pub.del key1 key2 key3 ...
```

where the items key1, key2, etc. are a set of keys that will find the paper, as with the *lookbib* command. That is, if

```
lookbib aho hirschberg ullman
```

will find a paper,

```
pub.del aho hirschberg ullman
```

deletes it. Upper and lower case are equivalent in keys; the command

```
pub.del Aho Hirschberg Ullman
```

is an equivalent *pub.del* command. The *pub.del* command will print the entry being deleted. It also gives the name of a "bibxxx" file on which the deletion command is stored. The actual deletion is not done until the changes, additions, etc. are processed, as with the *pub.chg* command. If, after seeing the item to be deleted, you change your mind about throwing it away, delete the "bibxxx" file and the delete request disappears. Again, if the list of keys does not uniquely identify one paper, an error message is given.

Remember that the default versions of the commands described here edit a public data base. Do not delete items unless you are sure deletion is proper; usually this means that there are duplicate entries for the same paper. Otherwise, view requests for deletion with skepticism; even if one person has no need for a particular item in the data base, someone else may want it there.

If an item is correct, but should not appear in the "List of Publications" as normally produced, add the line

```
%K DNL
```

to the item. This preserves the item intact, but implies "Do Not List" to the to the commands that print publication lists. The DNL line is normally used for some technical reports, minor memoranda, or other low-grade publications.

*Update and reindex.* When you have completed a session of changes, you should type the command

```
pub.run file1 file2 ...
```

where the names "file1", ... are the new files of additions you have prepared. You need not list the "bibxxx" files representing changes and deletions; they are processed automatically. All of the new items are edited into the standard public data base, and then a new index is made. This process takes about one minute of processor time. The index is not made by re-analyzing and re-sorting the entire data base; the new or changed items are indexed in the usual way and then merged with the previous data files. A complete re-index would be much slower for small changes.

Normally, you should execute *pub.run* just before you logoff after performing some edit requests. However, if you don't, the various change request files remain in your directory until you finally do execute *pub.run*. When the changes are processed, the "bibxxx" files are deleted. It is not desirable to wait too long before processing changes, however, to avoid conflicts with someone else who wishes to change the same file. If executing *pub.run* produces the message "File bibxxx too old" it means that someone else has been editing the same file between the time you prepared your changes, and the time you typed *pub.run*. You must delete such old change files and re-enter them.

Note that although *pub.run* discards the "bibxxx" files after processing them, your files of additions are left around even after *pub.run* is finished. If they were typed in only for purposes of updating the data base, you may delete them after they have been processed by *pub.run*.

*Example.* Suppose, for example, that you wish to

- (1) Add to the data base the memos "The Dilogarithm Function of a Real Argument" by R. Morris, and "UNIX Software Distribution by Communication Link," by M. E. Lesk and A. S. Cohen;
- (2) Delete from the data base the item "Cheap Typesetters", by M. E. Lesk, SIGLASH Newsletter, 1973; and
- (3) Change "J. Assoc. Comp. Mach." to "Jour. ACM" in the citation for Aho, Hirschberg, and Ullman shown above.

The procedure would be as follows. First, you would make a file containing the additions, here called "new.1", in the normal way using the UNIX editor. In the script shown below, the computer prompts are in italics.

```
$ ed new.1
?
a
%T The Dilogarithm Function of a Real Argument
%A Robert Morris
%M TM 78-1271-1
%D 1978

%T UNIX Software Distribution by Communication Link
%A M. E. Lesk
%A A. S. Cohen
%M TM 78-1274-1, 78-8234-1
%D 1978
w new.1
199
q
```

Next you would specify the deletion, which would be done with the *pub.del* command:

```
$ pub.del lesk cheap typesetters siglash
to which the computer responds:
```

```
Will delete: (file bib176)

%T Cheap Typesetters
%A M. E. Lesk
%J ACM SIGLASH Newsletter
%V 6
%N 4
%P 14-16
%D October 1973
```

And then you would extract the Aho, Hirschberg and Ullman paper. The dialogue involved is shown below. First run *pub.chg* to extract the paper; it responds by printing the citation and informing you that it was placed on file *bib123*. That file is then edited.

```
$ pub.chg aho hirschberg ullman
Extracting as file bib123
%T Bounds on the Complexity of the Maximal
Common Subsequence Problem
%A A. V. Aho
%A D. S. Hirschberg
%A J. D. Ullman
%J J. Assoc. Comp. Mach.
%V 23
%N 1
%P 1-12
%M TM 75-1271-7
%D Jan. 1976
```

```
$ ed bib123
312
/Assoc/s/ J/ Jour/p
%J Jour. Assoc. Comp. Mach.
s/Assoc.*/ACM/p
%J Jour. ACM
1,$p
%# /usr/dict/papers/p76 233 245 change
%T Bounds on the Complexity of the Maximal
Common Subsequence Problem
%A A. V. Aho
%A D. S. Hirschberg
%A J. D. Ullman
%J Jour. ACM
%V 23
%N 1
%P 1-12
%M TM 75-1271-7
%D Jan. 1976
```

```
w
292
q
$
```

Finally, execute *pub.run* , making sure to remember that you have prepared a new file “new.1”:

```
$ pub.run new.1
```

Currently, this takes about 1 minute of 11/70 processor time.

## 2. Printing a Publication List

There are two commands for printing a publication list, depending on whether you want to print one person’s list, or the list of many people. To print a list for one person, use the *pub.indiv* command:

```
pub.indiv M Lesk
```

This runs off the list for M. Lesk and puts it in file “output”. Note that no ‘.’ is given after the initial. In case of ambiguity two initials can be used. Similarly, to get the list for group of people, say

```
pub.org xxx
```

which prints all the publications of the members of organization *xxx* , taking the names for the list in the file */usr/dict/papers/centlist/xxx* . This command should normally be run in the background; it takes perhaps 15

minutes. Two options are available with these commands:

```
pub.indiv -p M Lesk
```

prints only the papers, leaving out unpublished notes, patents, etc. Also

```
pub.indiv -t M Lesk | gcat
```

prints a typeset copy, instead of a computer printer copy. In this case it has been directed to an alternate typesetter with the 'gcat' command. These options may be used together, and may be used with the *pub.org* command as well. For example, to print only the papers for all of organization *zzz* and typeset them, you could type

```
pub.center -t -p zzz | gcat &
```

These publication lists are printed double column with a citation style taken from a set of publication list macros; the macros, of course, can be changed easily to adjust the format of the lists.

## Some Applications of Inverted Indexes on the UNIX System

*M. E. Lesk*

Bell Laboratories  
Murray Hill, New Jersey 07974

### ABSTRACT

#### I. Some Applications of Inverted Indexes – Overview

This memorandum describes a set of programs which make inverted indexes to UNIX\* text files, and their application to retrieving and formatting citations for documents prepared using *troff*.

These indexing and searching programs make keyword indexes to volumes of material too large for linear searching. Searches for combinations of single words can be performed quickly. The programs are divided into two phases. The first makes an index from the original data; the second searches the index and retrieves items. Both of these phases are further divided into two parts to separate the data-dependent and algorithm dependent code.

The major current application of these programs is the *troff* preprocessor *refer*. A list of 4300 references is maintained on line, containing primarily papers written and cited by local authors. Whenever one of these references is required in a paper, a few words from the title or author list will retrieve it, and the user need not bother to re-enter the exact citation. Alternatively, authors can use their own lists of papers.

This memorandum is of interest to those who are interested in facilities for searching large but relatively unchanging text files on the UNIX system, and those who are interested in handling bibliographic citations with UNIX *troff*.

#### II. Updating Publication Lists

This section is a brief note describing the auxiliary programs for managing the updating processing. It is written to aid clerical users in maintaining lists of references. Primarily, the programs described permit a large amount of individual control over the content of publication lists while retaining the usefulness of the files to other users.

#### III. Manual Pages

This section contains the pages from the UNIX programmer's manual for the *lookall*, *pubindex*, and *refer* commands. It is useful for reference.

---

\* UNIX is a Trademark of Bell Laboratories.

These lines are the only input used to make the index. The first field (the file name, byte position, and byte count) is the tag of the item and can be used to retrieve it quickly. Normally, an item is either a whole file or a section of a file delimited by blank lines. After the tab, the second field contains the keys. The keys, if selected by the automatic program, are any alphanumeric strings which are not among the 100 most frequent words in English and which are not entirely numeric (except for four-digit numbers beginning 19, which are accepted as dates). Keys are truncated to six characters and converted to lower case. Some selection is needed if the original items are very large. We normally just take the first *n* keys, with *n* less than 100 or so; this replaces any attempt at intelligent selection. One file in our system is a complete English dictionary; it would presumably be retrieved for all queries.

To generate an inverted index to the list of record tags and keys, the keys are hashed and sorted to produce an index. What is wanted, ideally, is a series of lists showing the tags associated with each key. To condense this, what is actually produced is a list showing the tags associated with each hash code, and thus with some set of keys. To speed up access and further save space, a set of three or possibly four files is produced. These files are:

File	Contents
<i>entry</i>	Pointers to posting file for each hash code
<i>posting</i>	Lists of tag pointers for each hash code
<i>tag</i>	Tags for each item
<i>key</i>	Keys for each item (optional)

The posting file comprises the real data: it contains a sequence of lists of items posted under each hash code. To speed up searching, the entry file is an array of pointers into the posting file, one per potential hash code. Furthermore, the items in the lists in the posting file are not referred to by their complete tag, but just by an address in the tag file, which gives the complete tags. The key file is optional and contains a copy of the keys used in the indexing.

The searching process starts with a query, containing several keys. The goal is to obtain all items which were indexed under these keys. The query keys are hashed, and the pointers in the entry file used to access the lists in the posting file. These lists are addresses in the tag file of documents posted under the hash codes derived from the query. The common items from all lists are determined; this must include the items indexed by every key, but may also contain some items which are false drops, since items referenced by the correct hash codes need not actually have contained the correct keys. Normally, if there are several keys in the query, there are not likely to be many false drops in the final combined list even though each hash code is somewhat ambiguous. The actual tags are then obtained from the tag file, and to guard against the possibility that an item has false-dropped on some hash code in the query, the original items are normally obtained from the delivery program (4) and the query keys checked against them by string comparison.

Usually, therefore, the check for bad drops is made against the original file. However, if the key derivation procedure is complex, it may be preferable to check against the keys fed to program (2). In this case the optional key file which contains the keys associated with each item is generated, and the item tag is supplemented by a string

;start,length

which indicates the starting byte number in the key file and the length of the string of keys for each item. This file is not usually necessary with the present key-selection program, since the keys always appear in the original document.

There is also an option (-C*n*) for coordination level searching. This retrieves items which match all but *n* of the query keys. The items are retrieved in the order of the number of keys that they match. Of course, *n* must be less than the number of query keys (nothing is retrieved unless it matches at least one key).

As an example, consider one set of 4377 references, comprising 660,000 bytes. This included 51,000 keys, of which 5,900 were distinct keys. The hash table is kept full to save space (at the expense of time); 995 of 997 possible hash codes were used. The total set of index files (no key file) included 171,000 bytes, about 26% of the original file size. It took 8 minutes of processor time to hash, sort, and write the index.

To search for a single query with the resulting index took 1.9 seconds of processor time, while to find the same paper with a sequential linear search using *grep* (reading all of the tags and keys) took 12.3 seconds of processor time.

We have also used this software to index all of the English stored on our UNIX system. This is the index searched by the *lookall* command. On a typical day there were 29,000 files in our user file system, containing about 152,000,000 bytes. Of these 5,300 files, containing 32,000,000 bytes (about 21%) were English text. The total number of 'words' (determined mechanically) was 5,100,000. Of these 227,000 were selected as keys; 19,000 were distinct, hashing to 4,900 (of 5,000 possible) different hash codes. The resulting inverted file indexes used 845,000 bytes, or about 2.6% of the size of the original files. The particularly small indexes are caused by the fact that keys are taken from only the first 50 non-common words of some very long input files.

Even this large *lookall* index can be searched quickly. For example, to find this document by looking for the keys "lesk inverted indexes" required 1.7 seconds of processor time and system time. By comparison, just to search the 800,000 byte dictionary (smaller than even the inverted indexes, let alone the 32,000,000 bytes of text files) with *grep* takes 29 seconds of processor time. The *lookall* program is thus useful when looking for a document which you believe is stored on-line, but do not know where. For example, many memos from the Computing Science Research Center are in its UNIX file system, but it is often difficult to guess where a particular memo might be (it might have several authors, each with many directories, and have been worked on by a secretary with yet more directories). Instructions for the use of the *lookall* command are given in the manual section, shown in the appendix to this memorandum.

The only indexes maintained routinely are those of publication lists and all English files. To make other indexes, the programs for making keys, sorting them, searching the indexes, and delivering answers must be used. Since they are usually invoked as parts of higher-level commands, they are not in the default command directory, but are available to any user in the directory */usr/lib/refer*. Three programs are of interest: *mkey*, which isolates keys from input files; *inv*, which makes an index from a set of keys; and *hunt*, which searches the index and delivers the items. Note that the two parts of the retrieval phase are combined into one program, to avoid the excessive system work and delay which would result from running these as separate processes.

These three commands have a large number of options to adapt to different kinds of input. The user not interested in the detailed description that now follows may skip to section 3, which describes the *refer* program, a packaged-up version of these tools specifically oriented towards formatting references.

**Make Keys.** The program *mkey* is the key-making program corresponding to step (1) in phase A. Normally, it reads its input from the file names given as arguments, and if there are no arguments it reads from the standard input. It assumes that blank lines in the input delimit separate items, for each of which a different line of keys should be generated. The lines of keys are written on the standard output. Keys are any alphanumeric string in the input not among the most frequent words in English and not entirely numeric (except that all-numeric strings are acceptable if they are between 1900 and 1999). In the output, keys are translated to lower case, and truncated to six characters in length; any associated punctuation is removed. The following flag arguments are recognized by *mkey*:

- c name** Name of file of common words; default is */usr/lib/eign*.
- f name** Read a list of files from *name* and take each as an input argument.
- i chars** Ignore all lines which begin with '%' followed by any character in *chars*.
- kn** Use at most *n* keys per input item.
- ln** Ignore items shorter than *n* letters long.
- nm** Ignore as a key any word in the first *m* words of the list of common English words. The default is 100.
- s** Remove the labels (*file:start,length*) from the output; just give the keys. Used when searching rather than indexing.
- w** Each whole file is a separate item; blank lines in files are irrelevant.

The normal arguments for indexing references are the defaults, which are *-c /usr/lib/eign*, *-n100*, and *-l3*. For searching, the *-s* option is also needed. When the big *lookall* index of all English files is run, the options are *-w*, *-k50*, and *-f (filelist)*. When running on textual input, the *mkey* program processes

about 1000 English words per processor second. Unless the *-k* option is used (and the input files are long enough for it to take effect) the output of *mkey* is comparable in size to its input.

**Hash and invert.** The *inv* program computes the hash codes and writes the inverted files. It reads the output of *mkey* and writes the set of files described earlier in this section. It expects one argument, which is used as the base name for the three (or four) files to be written. Assuming an argument of *Index* (the default) the entry file is named *Index.ia*, the posting file *Index.ib*, the tag file *Index.ic*, and the key file (if present) *Index.id*. The *inv* program recognizes the following options:

- a** Append the new keys to a previous set of inverted files, making new files if there is no old set using the same base name.
- d** Write the optional key file. This is needed when you can not check for false drops by looking for the keys in the original inputs, i.e. when the key derivation procedure is complicated and the output keys are not words from the input files.
- hn** The hash table size is *n* (default 997); *n* should be prime. Making *n* bigger saves search time and spends disk space.
- i[u] name** Take input from file *name*, instead of the standard input; if **u** is present *name* is unlinked when the sort is started. Using this option permits the sort scratch space to overlap the disk space used for input keys.
- n** Make a completely new set of inverted files, ignoring previous files.
- p** Pipe into the sort program, rather than writing a temporary input file. This saves disk space and spends processor time.
- v** Verbose mode; print a summary of the number of keys which finished indexing.

About half the time used in *inv* is in the contained sort. Assuming the sort is roughly linear, however, a guess at the total timing for *inv* is 250 keys per second. The space used is usually of more importance: the entry file uses four bytes per possible hash (note the *-h* option), and the tag file around 15-20 bytes per item indexed. Roughly, the posting file contains one item for each key instance and one item for each possible hash code; the items are two bytes long if the tag file is less than 65336 bytes long, and the items are four bytes wide if the tag file is greater than 65336 bytes long. To minimize storage, the hash tables should be over-full; for most of the files indexed in this way, there is no other real choice, since the *entry* file must fit in memory.

**Searching and Retrieving.** The *hunt* program retrieves items from an index. It combines, as mentioned above, the two parts of phase (B): search and delivery. The reason why it is efficient to combine delivery and search is partly to avoid starting unnecessary processes, and partly because the delivery operation must be a part of the search operation in any case. Because of the hashing, the search part takes place in two stages: first items are retrieved which have the right hash codes associated with them, and then the actual items are inspected to determine false drops, i.e. to determine if anything with the right hash codes doesn't really have the right keys. Since the original item is retrieved to check on false drops, it is efficient to present it immediately, rather than only giving the tag as output and later retrieving the item again. If there were a separate key file, this argument would not apply, but separate key files are not common.

Input to *hunt* is taken from the standard input, one query per line. Each query should be in *mkey -s* output format; all lower case, no punctuation. The *hunt* program takes one argument which specifies the base name of the index files to be searched. Only one set of index files can be searched at a time, although many text files may be indexed as a group, of course. If one of the text files has been changed since the index, that file is searched with *fgrep*; this may occasionally slow down the searching, and care should be taken to avoid having many out of date files. The following option arguments are recognized by *hunt*:

- a** Give all output; ignore checking for false drops.
- Cn** Coordination level *n*; retrieve items with not more than *n* terms of the input missing; default *C0*, implying that each search term must be in the output items.

- F[ynd]** “-Fy” gives the text of all the items found; “-Fn” suppresses them. “-Fd” where *d* is an integer gives the text of the first *d* items. The default is -Fy.
- g** Do not use *fgrep* to search files changed since the index was made; print an error comment instead.
- i string** Take *string* as input, instead of reading the standard input.
- l n** The maximum length of internal lists of candidate items is *n*; default 1000.
- o string** Put text output (“-Fy”) in *string*; of use *only* when invoked from another program.
- p** Print hash code frequencies; mostly for use in optimizing hash table sizes.
- T[ynd]** “-Ty” gives the tags of the items found; “-Tn” suppresses them. “-Td” where *d* is an integer gives the first *d* tags. The default is -Tn.
- t string** Put tag output (“-Ty”) in *string*; of use *only* when invoked from another program.

The timing of *hunt* is complex. Normally the hash table is overfull, so that there will be many false drops on any single term; but a multi-term query will have few false drops on all terms. Thus if a query is underspecified (one search term) many potential items will be examined and discarded as false drops, wasting time. If the query is overspecified (a dozen search terms) many keys will be examined only to verify that the single item under consideration has that key posted. The variation of search time with number of keys is shown in the table below. Queries of varying length were constructed to retrieve a particular document from the file of references. In the sequence to the left, search terms were chosen so as to select the desired paper as quickly as possible. In the sequence on the right, terms were chosen inefficiently, so that the query did not uniquely select the desired document until four keys had been used. The same document was the target in each case, and the final set of eight keys are also identical; the differences at five, six and seven keys are produced by measurement error, not by the slightly different key lists.

Efficient Keys				Inefficient Keys			
No. keys	Total drops (incl. false)	Retrieved Documents	Search time (seconds)	No. keys	Total drops (incl. false)	Retrieved Documents	Search time (seconds)
1	15	3	1.27	1	68	55	5.96
2	1	1	0.11	2	29	29	2.72
3	1	1	0.14	3	8	8	0.95
4	1	1	0.17	4	1	1	0.18
5	1	1	0.19	5	1	1	0.21
6	1	1	0.23	6	1	1	0.22
7	1	1	0.27	7	1	1	0.26
8	1	1	0.29	8	1	1	0.29

As would be expected, the optimal search is achieved when the query just specifies the answer; however, overspecification is quite cheap. Roughly, the time required by *hunt* can be approximated as 30 milliseconds per search key plus 75 milliseconds per dropped document (whether it is a false drop or a real answer). In general, overspecification can be recommended; it protects the user against additions to the data base which turn previously uniquely-answered queries into ambiguous queries.

The careful reader will have noted an enormous discrepancy between these times and the earlier quoted time of around 1.9 seconds for a search. The times here are purely for the search and retrieval: they are measured by running many searches through a single invocation of the *hunt* program alone. Usually, the UNIX command processor (the shell) must start both the *mkey* and *hunt* processes for each query, and arrange for the output of *mkey* to be fed to the *hunt* program. This adds a fixed overhead of about 1.7 seconds of processor time to any single search. Furthermore, remember that all these times are processor times: on a typical morning on our PDP 11/70 system, with about one dozen people logged on, to obtain 1 second of processor time for the search program took between 2 and 12 seconds of real time, with a median of 3.9 seconds and a mean of 4.8 seconds. Thus, although the work involved in a single search may be only 200 milliseconds, after you add the 1.7 seconds of startup processor time and then assume a 4:1

elapsed/processor time ratio, it will be 8 seconds before any response is printed.

### 5. Selecting and Formatting References for TROFF

The major application of the retrieval software is *refer*, which is a *troff* preprocessor like *eqn*. kernighan cherry acm 1975 It scans its input looking for items of the form

```
.[
  imprecise citation
.]
```

where an imprecise citation is merely a string of words found in the relevant bibliographic citation. This is translated into a properly formatted reference. If the imprecise citation does not correctly identify a single paper (either selecting no papers or too many) a message is given. The data base of citations searched may be tailored to each system, and individual users may specify their own citation files. On our system, the default data base is accumulated from the publication lists of the members of our organization, plus about half a dozen personal bibliographies that were collected. The present total is about 4300 citations, but this increases steadily. Even now, the data base covers a large fraction of local citations.

For example, the reference for the *eqn* paper above was specified as

```
...
preprocessor like
.I eqn.
.[
kernighan cherry acm 1975
.]
It scans its input looking for items
...
```

This paper was itself printed using *refer*. The above input text was processed by *refer* as well as *tbl* and *troff* by the command

```
refer memo-file | tbl | troff -ms
```

and the reference was automatically translated into a correct citation to the ACM paper on mathematical typesetting.

The procedure to use to place a reference in a paper using *refer* is as follows. First, use the *lookbib* command to check that the paper is in the data base and to find out what keys are necessary to retrieve it. This is done by typing *lookbib* and then typing some potential queries until a suitable query is found. For example, had one started to find the *eqn* paper shown above by presenting the query

```
$ lookbib
kernighan cherry
(EOT)
```

*lookbib* would have found several items; experimentation would quickly have shown that the query given above is adequate. Overspecifying the query is of course harmless; it is even desirable, since it decreases the risk that a document added to the publication data base in the future will be retrieved in addition to the intended document. The extra time taken by even a grossly overspecified query is quite small. A particularly careful reader may have noticed that “acm” does not appear in the printed citation; we have supplemented some of the data base items with extra keywords, such as common abbreviations for journals or other sources, to aid in searching.

If the reference is in the data base, the query that retrieved it can be inserted in the text, between *.[* and *.]* brackets. If it is not in the data base, it can be typed into a private file of references, using the format discussed in the next section, and then the *-p* option used to search this private file. Such a command might read (if the private references are called *myfile*)

```
refer -p myfile document | tbl | eqn | troff -ms . . .
```

where *tbl* and/or *eqn* could be omitted if not needed. The use of the *-ms* macros less typing documents

unix gcos or some other macro package, however, is essential. *Refer* only generates the data for the references; exact formatting is done by some macro package, and if none is supplied the references will not be printed.

By default, the references are numbered sequentially, and the *-ms* macros format references as footnotes at the bottom of the page. This memorandum is an example of that style. Other possibilities are discussed in section 5 below.

### 6. Reference Files.

A reference file is a set of bibliographic references usable with *refer*. It can be indexed using the software described in section 2 for fast searching. What *refer* does is to read the input document stream, looking for imprecise citation references. It then searches through reference files to find the full citations, and inserts them into the document. The format of the full citation is arranged to make it convenient for a macro package, such as the *-ms* macros, to format the reference for printing. Since the format of the final reference is determined by the desired style of output, which is determined by the macros used, *refer* avoids forcing any kind of reference appearance. All it does is define a set of string registers which contain the basic information about the reference; and provide a macro call which is expanded by the macro package to format the reference. It is the responsibility of the final macro package to see that the reference is actually printed; if no macros are used, and the output of *refer* fed untranslated to *troff*, nothing at all will be printed.

The strings defined by *refer* are taken directly from the files of references, which are in the following format. The references should be separated by blank lines. Each reference is a sequence of lines beginning with % and followed by a key-letter. The remainder of that line, and successive lines until the next line beginning with %, contain the information specified by the key-letter. In general, *refer* does not interpret the information, but merely presents it to the macro package for final formatting. A user with a separate macro package, for example, can add new key-letters or use the existing ones for other purposes without bothering *refer*.

The meaning of the key-letters given below, in particular, is that assigned by the *-ms* macros. Not all information, obviously, is used with each citation. For example, if a document is both an internal memorandum and a journal article, the macros ignore the memorandum version and cite only the journal article. Some kinds of information are not used at all in printing the reference; if a user does not like finding references by specifying title or author keywords, and prefers to add specific keywords to the citation, a field is available which is searched but not printed (**K**).

The key letters currently recognized by *refer* and *-ms*, with the kind of information implied, are:

Key	Information specified	Key	Information specified
A	Author's name	N	Issue number
B	Title of book containing item	O	Other information
C	City of publication	P	Page(s) of article
D	Date	R	Technical report reference
E	Editor of book containing item	T	Title
G	Government (NTIS) ordering number	V	Volume number
I	Issuer (publisher)		
J	Journal name	X	or
K	Keys (for searching)	Y	or
L	Label	Z	Information not used by <i>refer</i>
M	Memorandum label		

For example, a sample reference could be typed as:

```
%T Bounds on the Complexity of the Maximal
Common Subsequence Problem
%Z ctr127
%A A. V. Aho
%A D. S. Hirschberg
%A J. D. Ullman
%J J. ACM
%V 23
```

```
%N 1
%P 1-12
%M abcd-78
%D Jan. 1976
```

Order is irrelevant, except that authors are shown in the order given. The output of *refer* is a stream of string definitions, one for each of the fields of each reference, as shown below.

```
.]-
.ds [A authors' names ...
.ds [T title ...
.ds [J journal ...
...
.][ type-number
```

The *refer* program, in general, does not concern itself with the significance of the strings. The different fields are treated identically by *refer*, except that the X, Y and Z fields are ignored (see the `-i` option of *mkey*) in indexing and searching. All *refer* does is select the appropriate citation, based on the keys. The macro package must arrange the strings so as to produce an appropriately formatted citation. In this process, it uses the convention that the 'T' field is the title, the 'J' field the journal, and so forth.

The *refer* program does arrange the citation to simplify the macro package's job, however. The special macro `.]-` precedes the string definitions and the special macro `.][` follows. These are changed from the input `.[` and `.]` so that running the same file through *refer* again is harmless. The `.]-` macro can be used by the macro package to initialize. The `.][` macro, which should be used to print the reference, is given an argument *type-number* to indicate the kind of reference, as follows:

Value	Kind of reference
1	Journal article
2	Book
3	Article within book
4	Technical report
5	Bell Labs technical memorandum
0	Other

The type is determined by the presence or absence of particular fields in the citation (a journal article must have a 'J' field, a book must have an 'I' field, and so forth). To a small extent, this violates the above rule that *refer* does not concern itself with the contents of the citation; however, the classification of the citation in *troff* macros would require a relatively expensive and obscure program. Any macro writer may, of course, preserve consistency by ignoring the argument to the `.][` macro.

The reference is flagged in the text with the sequence

```
\*([.number\*(.)
```

where *number* is the footnote number. The strings `[.` and `.]` should be used by the macro package to format the reference flag in the text. These strings can be replaced for a particular footnote, as described in section 5. The footnote number (or other signal) is available to the reference macro `.][` as the string register `[F`. To simplify dealing with a text reference that occurs at the end of a sentence, *refer* treats a reference which follows a period in a special way. The period is removed, and the reference is preceded by a call for the string `<.` and followed by a call for the string `>.` For example, if a reference follows "end." it will appear as

```
end*(<.\*([.number\*(.)\*(>.
```

where *number* is the footnote number. The macro package should turn either the string `>.` or `<.` into a period and delete the other one. This permits the output to have either the form "end[31]." or "end.<sup>31</sup>" as the macro package wishes. Note that in one case the period precedes the number and in the other it follows the number.

In some cases users wish to suspend the searching, and merely use the reference macro formatting. That is, the user doesn't want to provide a search key between `.[` and `.]` brackets, but merely the reference lines

for the appropriate document. Alternatively, the user can wish to add a few fields to those in the reference as in the standard file, or override some fields. Altering or replacing fields, or supplying whole references, is easily done by inserting lines beginning with %; any such line is taken as direct input to the reference processor rather than keys to be searched. Thus

```
.[  
key1 key2 key3 ...  
%Q New format item  
%R Override report name  
.]
```

makes the indicates changes to the result of searching for the keys. All of the search keys must be given before the first % line.

If no search keys are provided, an entire citation can be provided in-line in the text. For example, if the *eqn* paper citation were to be inserted in this way, rather than by searching for it in the data base, the input would read

```
...  
preprocessor like  
.I eqn.  
.[  
%A B. W. Kernighan  
%A L. L. Cherry  
%T A System for Typesetting Mathematics  
%J Comm. ACM  
%V 18  
%N 3  
%P 151-157  
%D March 1975  
.]  
It scans its input looking for items  
...
```

This would produce a citation of the same appearance as that resulting from the file search.

As shown, fields are normally turned into *troff* strings. Sometimes users would rather have them defined as macros, so that other *troff* commands can be placed into the data. When this is necessary, simply double the control character % in the data. Thus the input

```
.[  
%V 23  
%%M  
Bell Laboratories,  
Murray Hill, N.J. 07974  
.]
```

is processed by *refer* into

```
.ds [V 23  
.de [M  
Bell Laboratories,  
Murray Hill, N.J. 07974  
..
```

The information after %%M is defined as a macro to be invoked by .[M while the information after %V is turned into a string to be invoked by \\*(V. At present *-ms* expects all information as strings.

## 7. Collecting References and other Refer Options

Normally, the combination of *refer* and *-ms* formats output as *troff* footnotes which are consecutively numbered and placed at the bottom of the page. However, options exist to place the references at the end; to arrange references alphabetically by senior author; and to indicate references by strings in the text of the form [Name1975a] rather than by number. Whenever references are not placed at the bottom of a page identical references are coalesced.

For example, the *-e* option to *refer* specifies that references are to be collected; in this case they are output whenever the sequence

```
.[
$LISTS
.]
```

is encountered. Thus, to place references at the end of a paper, the user would run *refer* with the *-e* option and place the above \$LISTS commands after the last line of the text. *Refer* will then move all the references to that point. To aid in formatting the collected references, *refer* writes the references preceded by the line

```
.J<
```

and followed by the line

```
.J>
```

to invoke special macros before and after the references.

Another possible option to *refer* is the *-s* option to specify sorting of references. The default, of course, is to list references in the order presented. The *-s* option implies the *-e* option, and thus requires a

```
.[
$LISTS
.]
```

entry to call out the reference list. The *-s* option may be followed by a string of letters, numbers, and '+' signs indicating how the references are to be sorted. The sort is done using the fields whose key-letters are in the string as sorting keys; the numbers indicate how many of the fields are to be considered, with '+' taken as a large number. Thus the default is *-sAD* meaning "Sort on senior author, then date." To sort on all authors and then title, specify *-sA+T*. And to sort on two authors and then the journal, write *-sA2J*.

Other options to *refer* change the signal or label inserted in the text for each reference. Normally these are just sequential numbers, and their exact placement (within brackets, as superscripts, etc.) is determined by the macro package. The *-l* option replaces reference numbers by strings composed of the senior author's last name, the date, and a disambiguating letter. If a number follows the *l* as in *-l3* only that many letters of the last name are used in the label string. To abbreviate the date as well the form *-lm,n* shortens the last name to the first *m* letters and the date to the last *n* digits. For example, the option *-l3,2* would refer to the *eqn* paper (reference 3) by the signal *Ker75a*, since it is the first cited reference by Kernighan in 1975.

A user wishing to specify particular labels for a private bibliography may use the *-k* option. Specifying *-kx* causes the field *x* to be used as a label. The default is *L*. If this field ends in *-*, that character is replaced by a sequence letter; otherwise the field is used exactly as given.

If none of the *refer*-produced signals are desired, the *-b* option entirely suppresses automatic text signals.

If the user wishes to override the *-ms* treatment of the reference signal (which is normally to enclose the number in brackets in *nroff* and make it a superscript in *troff*) this can be done easily. If the lines *.[* or *.]* contain anything following these characters, the remainders of these lines are used to surround the reference signal, instead of the default. Thus, for example, to say "See reference (2)." and avoid "See reference.<sup>2</sup>" the input might appear

```
See reference
.[ (
imprecise citation ...
.]).
```

Note that blanks are significant in this construction. If a permanent change is desired in the style of reference signals, however, it is probably easier to redefine the strings [ and .] (which are used to bracket each signal) than to change each citation.

Although normally *refer* limits itself to retrieving the data for the reference, and leaves to a macro package the job of arranging that data as required by the local format, there are two special options for rearrangements that can not be done by macro packages. The `-c` option puts fields into all upper case (CAPS-SMALL CAPS in *troff* output). The key-letters indicated what information is to be translated to upper case follow the `c`, so that `-cAJ` means that authors' names and journals are to be in caps. The `-a` option writes the names of authors last name first, that is *A. D. Hall, Jr.* is written as *Hall, A. D. Jr.* The citation form of the *Journal of the ACM*, for example, would require both `-cA` and `-a` options. This produces authors' names in the style *KERNIGHAN, B. W. AND CHERRY, L. L.* for the previous example. The `-a` option may be followed by a number to indicate how many author names should be reversed; `-a1` (without any `-c` option) would produce *Kernighan, B. W. and L. L. Cherry*, for example.

Finally, there is also the previously-mentioned `-p` option to let the user specify a private file of references to be searched before the public files. Note that *refer* does not insist on a previously made index for these files. If a file is named which contains reference data but is not indexed, it will be searched (more slowly) by *refer* using *fgrep*. In this way it is easy for users to keep small files of new references, which can later be added to the public data bases.
